# 16-Channel Constant-Current Latched LEDDriver with Open LED Detection and Dot Correction 

## Features and Benefits

- 3.0 to 5.5 V logic supply range
- Schmitt trigger inputs for improved noise immunity
- Power-On Reset (POR)
- Up to 80 mA constant-current sinking outputs
- LED open circuit detection (LOD)
- Dot correction (DC) for adjusting LED light intensity on each channel with 7-bit resolution
- Low-power CMOS logic and latches
- High data input rate up to 30 MHz
- Active output pull-ups with enable/disable
- 20 ns typical staggering delay between outputs
- Internal UVLO and thermal shutdown (TSD) circuitry
- Fault output flags for an LED open circuit (LOD) or a thermal shutdown (TSD) condition

## Package: 32 Contact QFN (suffix ET)

$5 \mathrm{~mm} \times 5 \mathrm{~mm}$
0.90 mm nominal overall height

## Description

The A6285 is designed for LED display applications. This BiCMOS device includes an On/Off shift register, a Dot Correction (DC) shift register, accompanying data latches, and 16 MOS constant-current sink drivers with active pull-ups that can be enabled or disabled as required by the application.

The CMOS shift registers and latches allow direct interfacing with microprocessor-based systems. With a 3.3 or 5 V logic supply, typical serial data input rates can reach up to 30 MHz . The LED drive current level can be set by a single external resistor, selected by the application designer. A CMOS serial data output permits cascading of multiple devices in applications requiring additional drive lines.

Individual LED light intensity can be adjusted to correct for light intensity variations by using the Dot Correction feature.

Open LED connections can be detected, and then signaled back to the host microprocessor through the serial data output (SDO pin). The FAULT output flags an LED open circuit (LOD) condition or a thermal shutdown (TSD) condition. A staggering delay on the load outputs during ON/OFF transitions helps to reduce ground bounce.

Typical Application

## 16-Channel Constant-Current Latched LED Driver with Open LED Detection and Dot Correction

## Description (continued)

The device is available in a 32 -lead QFN (package ET), with an exposed thermal pad. It is lead $(\mathrm{Pb})$ free with $100 \%$ matte tin leadframe plating.

Applications include the following:

- Display backlighting
- Monocolor, multicolor, or full-color LED display
- Monocolor, multicolor, LED Signboard
- Multicolor LED lighting

Selection Guide

| Part Number | Package | Packing (estimated) |
| :--- | :--- | :--- |
| A6285EET-T | $5 \times 5 \mathrm{~mm}$ QFN, 32 pin, exposed thermal pad | 73 pieces per tube |
| A6285EETTR-T | $5 \times 5 \mathrm{~mm}$ QFN, 32 pin, exposed thermal pad | 1500 pieces per 7 -in reel |

Absolute Maximum Ratings

| Characteristic | Symbol | Notes | Min. | Max. | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Supply Voltage* | $V_{D D}$ |  | -0.3 | 5.5 | V |

Terminal List Table

| Name | Number | Description |
| :---: | :---: | :---: |
| OE | 30 | Output Enable input. Active low. When $\overline{\mathrm{OE}}=$ High, all OUTx outputs are forced OFF. When $\overline{\mathrm{OE}}=\mathrm{Low}$, ON/OFF of OUTx outputs are controlled by input data. |
| GND | 29 | Logic supply ground. |
| PE | 23 | Active Pull-up Enable. When connected to LED Load Supply ( $\mathrm{V}_{\text {LED }}$ ) = enabled, when connected to PGND = disabled. |
| REXT | 27 | Reference current input/output terminal. |
| MODE | 26 | Logic input, Mode select. When MODE = Low, then SDI, SDO, CLK, LE are connected to ON/OFF control logic. When MODE = High, SDI, SDO, CLK, LE are connected to dot-correction logic. |
| NC | 2 | No connection. Not internally connected. |
| OUT0 | 3 |  |
| OUT1 | 4 |  |
| OUT2 | 6 |  |
| OUT3 | 7 |  |
| OUT4 | 8 |  |
| OUT5 | 9 |  |
| OUT6 | 11 |  |
| OUT7 | 12 |  |
| OUT8 | 13 | Constant current outputs. |
| OUT9 | 14 |  |
| OUT10 | 16 |  |
| OUT11 | 17 |  |
| OUT12 | 18 |  |
| OUT13 | 19 |  |
| OUT14 | 21 |  |
| OUT15 | 22 |  |
| PGND | 5, 10, 15, 20 | Power ground. |
| CLK | 32 | Data shift clock input. Note that the internal connections are switched by input at MODE pin. At CLK $\uparrow$, the shift-registers selected by MODE shift the data. |
| SDI | 1 | Serial Data In. Data input of serial data interface. |
| SDO | 24 | Serial Data Out. Data output of serial data interface. |
| VDD | 28 | Logic Supply. |
| FAULT | 25 | Error output. FAULT is open drain terminal. FAULT goes low when LOD or TSD detected. |
| LE | 31 | Latch Enable input. Note that the internal connections are switched by input at the MODE pin. At LE $\uparrow$, the latches selected by MODE get new data. |
| PAD | - | Exposed pad for enhanced thermal dissipation; not connected internally, connect to power ground plane. |

# 16-Channel Constant-Current Latched LED Driver with Open LED Detection and Dot Correction 

## Functional Description

Setting Maximum Channel Current The maximum output current per channel is set by a single external resistor, REXT, which is placed between the REXT pin and PGND. The voltage on REXT, $\mathrm{V}_{\text {EXT }}$, is set by an internal band gap. The maximum channel current is equivalent to the current flowing through REXT multiplied by 38.4. The maximum channel output current can be calculated as:
where:

$$
\begin{equation*}
I_{\mathrm{O}}(\max )=\frac{V_{\mathrm{EXT}}}{R_{\mathrm{EXT}}} \times 38.4 \tag{1}
\end{equation*}
$$

$\mathrm{V}_{\mathrm{EXT}}$ is 1.25 V typical, and
$\mathrm{R}_{\mathrm{EXT}}$ is the value of the user-selected external resistor, which should not be less than $600 \Omega$, corresponding to 80 mA .

Figure 4 shows the maximum per channel constant output current, $\mathrm{I}_{\mathrm{O}}(\max )$, of OUT0 to OUT15, versus $\mathrm{R}_{\text {EXT }}$, the value of the resistor between REXT terminal and ground.

Dot Correction The A6285 can independently fine-adjust the current of each output channel, a feature referred to as dot correction. This feature is used to compensate for the brightness deviations of the LEDs connected to the output channels, OUT0 through OUT15.

Each of the 16 channels can be programmed with a 7-bit word. The channel output can be adjusted in 128 steps from $0 \%$ to $100 \%$ of the maximum programmable per channel output current, $\mathrm{I}_{\mathrm{O}}(\max )$. Equation 2 determines the output current for each OUTx:

$$
\begin{equation*}
I_{\mathrm{O} x}=\frac{I_{\mathrm{O}}(\max ) \times D C_{x}}{127} \tag{2}
\end{equation*}
$$

where $\mathrm{DC}_{x}$ is the programmed dot-correction value $(0,1, \ldots 127)$ for each output channel.
Dot correction data is entered for all channels at the same time. The complete dot correction data format consists of sixteen 7-bit words, which form a 112 -bit $(16 \times 7)$ wide serial data packet. The data for each channel is sent in a continuous sequence, and all data is clocked in with the MSB first, as shown in figure 7.
To input data into the Dot Correction register, LE should be set low, and MODE must be set high. MODE sets the input shift register to 112-bit width. After all serial data is clocked in, a rising edge on the LE terminal latches the data into the Dot Correction
register. The timing sequence is shown in figure 9.
All Channel Output Enable-Disable All OUTx channels of the A6285 can switched off using the $\overline{\mathrm{OE}}$ pin. When $\overline{\mathrm{OE}}$ is set high, all OUTx outputs are disabled, regardless of the on/off status of any OUTx. When $\overline{\mathrm{OE}}$ is set to low, the on/off status of each OUTx is determined by the state of the latches in the On/Off register. $\overline{\mathrm{OE}}$ can be PWMed to control the average current, which controls the LED brightness of all outputs, in addition to the DC function.

Individual Channel Output Enable-Disable Each OUTx channel can be switched on or off independently. Each of the channels can be programmed with a 1-bit word.

On/off data is entered for all channels at the same time. The complete on/off data format consists of sixteen 1-bit words, which form a 16 -bit wide serial data packet. The data for each channel is sent in a continuous sequence, and all data is clocked in with the MSB first, as shown in figure 8.

To input data into the On/Off register, LE must be set low, and MODE must be set low. LE allows on/off data to enter the input shift register, and MODE sets the input shift register to 16-bit width. After all serial data is clocked in, a rising edge on the LE terminal latches the data into the On/Off register and moves the LOD data at the Open Circuit Detector into the input shift register. The timing sequence is shown in figure 9 .

Figure 7. Dot Correction (DC) data format

Figure 8. Individual output on-off data format

## 16-Channel Constant-Current Latched LED Driver with Open LED Detection and Dot Correction

Delay Between Outputs The A6285 has graduated delay circuits between outputs. The fixed delay time is 20 ns (typical). OUT0 has no delay, OUT1 has a 20 ns delay, OUT2 has a 40 ns delay, and so forth. This delay prevents large in-rush currents that create ground bounce, which reduces power supply bypass capacitor requirements when the outputs turn on. The delays work during switch on and switch off of each output channel.

Serial Interface Data Transfer Rate The A6285
includes a flexible serial data interface, which can be connected to a microcontroller or a digital signal processor. Only 3 pins are
required to input data into the device. The rising edge of a CLK signal shifts the data from SDI pin to the input shift register. After all data is clocked in, a rising edge of LE latches the serial data to the On/Off register. All data is clocked in with the MSB first, while LE is set low.

Multiple A6285 devices can be cascaded by connecting the SDOpin of one device with the SDI pin of the following device. The SDO pin can also be connected to the microcontroller or microprocessor in order to transmit LOD information from the A6285.

Figure 9. Output on-off and Dot Correction timing

## 16-Channel Constant-Current Latched LED Driver with Open LED Detection and Dot Correction

Figure 10 shows an example application with $n$ cascaded A6285 devices connected to a controller. The maximum number of cascaded devices depends on the application system and the data transfer rate. The minimum data input transfer rate is calculated as follows:

$$
\begin{equation*}
f_{\text {CLK }}=112 \times f_{\text {UPDATE }} \times n \tag{3}
\end{equation*}
$$

where:
$\mathrm{f}_{\text {CLK }}$ is the minimum data input frequency for CLK and SDI,
$\mathrm{f}_{\text {UPDATE }}$ is the update rate of the entire cascaded system, and n is the number of cascaded A6285 devices.

Operating Modes The A6285 has two operating modes, determined by the MODE signal:

- On-Off mode (MODE = low)
- Dot Correction mode (MODE = high)

Fault Output, FAULT The open-drain output FAULT is used to report both of the fault flags, LOD and TSD. During normal operating conditions, the internal transistor connected to the FAULT pin is turned off. The voltage on FAULT is pulled up to $\mathrm{V}_{\mathrm{DD}}$ through a external pull-up resistor.

If an LOD or TSD condition is detected, the internal transistor is turned on, and FAULT is pulled to PGND. Because FAULT is an open-drain output, multiple ICs can be ORed together and pulled-
up to $\mathrm{V}_{\mathrm{DD}}$ with a single pull-up resistor, as shown in figure 10 . This reduces the number of signals needed to report faults.

To determine whether the fault is a TSD or an LOD, LOD can be masked by setting $\overline{\mathrm{OE}}=$ high. However, it cannot be determined if both a TSD and an LOD condition are present. The FAULT Truth Table is shown on page 11.
Active Pull-up Enable, PE The A6285 provides active pull-ups on each output determined by the PE pin. When the LED supply, $\mathrm{V}_{\text {LED }}$, is tied to the PE pin, the active pull-ups are enabled. When the PE pin is tied to ground, the active pull-ups are disabled. The Active Pull-up Enable is also current-limited to 2.8 mA typical, preventing possible damage to the device in the event of a short-to-ground. This feature can eliminate ghosting in multiplexing applications.

Undervoltage Lockout (UVLO) and Power-On Reset
(POR) The A6285 includes an internal undervoltage lockout circuit that disables the outputs in the event that the logic supply voltage drops below a minimum acceptable level. This feature prevents the display of erroneous information, a function necessary for some critical applications. A Power-On Reset (POR) is performed upon recovery of the logic supply voltage after a UVLO event and at power-up. During POR, all internal shift registers and latches are set to 0 .
Thermal Shutdown Protection and Fault Flag (TSD) The A6285 provides thermal protection when the device is overheated, typically a result of excessive power being dissipated in the outputs. If the junction temperature exceeds the threshold

Figure 10. Schematic of cascaded A6285 devices

# 16-Channel Constant-Current Latched LED Driver with Open LED Detection and Dot Correction 

temperature, $\mathrm{T}_{\mathrm{TSDF}}$, of $165^{\circ} \mathrm{C}$ (typical), all driver outputs will be turned off and a TSD fault will be flagged. The TSD flag will pull the FAULT output pin to PGND (low). After a $15^{\circ} \mathrm{C}$ (typical) drop in junction temperature, the outputs will turn back on and the FAULT pin will be pulled back to VDD (high). The input shift register and the latch register will remain active during a TSD event. Therefore, there is no need to reset the data in the output latches. However, the TSD cycle will continue until the thermal problem is corrected.
LED Open Detection (LOD) The A6285 provides LED open circuit detection. This circuit flags a fault and pulls the FAULT pin to PGND (low) if any of the 16 OUTx LEDs are open or disconnected from the circuit.

The LOD circuit flags a fault when all of the following conditions are met:

- $\overline{\mathrm{OE}}$ is set low
- The voltage at each OUTx pin is sampled after being turned on
- $\mathrm{V}_{\text {OUTx }}<\mathrm{V}_{\text {LOD }}$ ( 0.3 V typical)

MODE may be set either high or low. However, to perform a complete LOD cycle, which includes reading the LOD status of each OUTx, MODE must be set low.

A complete LOD cycle is described as follows:

1. On/Off data is clocked into the input shift register.
2. LE is pulsed to move the On/Off data into the On/Off Register. The data is moved on the rising edge of LE. If an LOD condition is present, the FAULT output is immediately pulled to PGND (low).
3. Data present at the Open Circuit Detector (sampled when data was moved into the On/Off Register on the previous transition of LE) is immediately moved into the input shift register on the same rising edge of LE.

If no LOD condition was previously detected, all 0 s are present at the Open Circuit Detector. Thus, all 0s are moved into the input shift register. This gives the appearance of "clearing"
the input shift register every time On/Off data is moved into the On/Off Register, although in reality, the previous LOD status is being moved into the input shift register.

If an LOD condition was previously detected, a 1 for each open LED will be moved from the Open Circuit Detector into the input shift register, where it can be read on the SDO pin.
4. The existing LOD condition is sampled within $2 \mu \mathrm{~s}$ of the outputs turning on and the resulting status data waits at the Open Circuit Detector until moved into the input shift register on the rising edge of the next LE pulse.
5. The cycle is repeated when new On/Off data is clocked into the input shift register. As new data is being clocked in, LOD status data is being clocked out of the SDO pin, where it can be read by a microprocessor.

Note: It is not necessary to load new On/Off data in order to view the LOD status waiting at the Open Circuit Detector. A second LE pulse will put the LOD data into the input shift register. However, LOD data that is presently in the input shift register will be moved into the On/Off Register, generating a "blank" display. Such a blank display may be undesirable; therefore, a second LE pulse should not be applied without first clocking in useful On/Off data for updating the display.

The update interval between LE pulses (LE1 to LE2 ), referred to as the LOD Sample and Read Time, $\mathrm{t}_{\text {LOD }}$, must be at least 1660 ns to allow for settling and staggered delays. Figure 11 shows the LOD serial data format. The FAULT truth table is shown below.

Figure 11. Individual output LOD data format

FAULT Truth Table

| Conditions |  |  | Fault Output |
| :---: | :---: | :---: | :---: |
| Junction Temperature | Outx Voltage | Output Enable, OE |  |
| $\mathrm{T}_{\mathrm{J}}<\mathrm{T}_{\text {TSD }}$ | Outx > V LOD | H | H |
| $\mathrm{T}_{\mathrm{J}}<\mathrm{T}_{\text {TSD }}$ | Outx < V LOD | H | H |
| $\mathrm{T}_{\mathrm{J}}<\mathrm{T}_{\text {TSD }}$ | Outx > V LOD | L | H |
| $\mathrm{T}_{\mathrm{J}}<\mathrm{T}_{\text {TSD }}$ | Outx < V LOD | L | L |
| $\mathrm{T}_{\mathrm{J}}>\mathrm{T}_{\text {TSD }}$ | Outx > V LOD | H | L |
| $\mathrm{T}_{\mathrm{J}}>\mathrm{T}_{\text {TSD }}$ | Outx < V LOD | H | L |
| $\mathrm{T}_{\mathrm{J}}>\mathrm{T}_{\text {TSD }}$ | Outx $>\mathrm{V}_{\text {LOD }}$ | L | L |
| $\mathrm{T}_{\mathrm{J}}>\mathrm{T}_{\text {TSD }}$ | Outx < V LOD | L | L |

# 16-Channel Constant-Current Latched LED Driver with Open LED Detection and Dot Correction 

## Application Information

## Load Supply Voltage ( $\mathrm{V}_{\text {LED }}$ )

These devices are designed to operate with driver voltage drops $\left(\mathrm{V}_{\mathrm{DS}}\right)$ of 1.0 to 3.0 V , with one or more LED forward voltages, $\mathrm{V}_{\mathrm{F}}$, of 1.2 to 4.0 V . If higher voltages are dropped across the driver, package power dissipation will increase significantly. To minimize package power dissipation, it is recommended to use the lowest possible load supply voltage, $\mathrm{V}_{\text {LED }}$, or to set any series voltage dropping, $\mathrm{V}_{\mathrm{DROP}}$, according to the following formula:

$$
\mathrm{V}_{\mathrm{DROP}}=\mathrm{V}_{\mathrm{LED}}-\mathrm{V}_{\mathrm{F}}-\mathrm{V}_{\mathrm{DS}},
$$

with $V_{D R O P}=I_{O} \times R_{D R O P}$ for a single driver or for a Zener diode $\left(\mathrm{V}_{\mathrm{Z}}\right)$, or for a series string of silicon diodes (approximately 0.7 V per diode) for a group of drivers (see figure 3). If the available voltage source will cause unacceptable power dissipation and series resistors or diodes are undesirable, a voltage regulator can be used to provide $V_{\text {LED }}$.

For reference, typical LED forward voltages are:

| LED Type | $\mathrm{V}_{\mathrm{F}}(\mathrm{V})$ |
| :---: | :---: |
| White | 3.5 to 4.0 |
| Blue | 3.0 to 4.0 |
| Green | 1.8 to 2.2 |
| Yellow | 2.0 to 2.1 |
| Amber | 1.9 to 2.65 |
| Red | 1.6 to 2.25 |
| Infrared | 1.2 to 1.5 |

## Pattern Layout

The logic and power grounds should be kept separate, terminated at one location. The exposed metal pad must be connected to a large power ground plane, allowing the copper to dissipate heat. Where multiple devices are cascaded, multilayer boards are recommended.
REXT should be placed as close as possible to the device, keeping a short distance between the REXT pin and ground.

Decoupling capacitors should be used liberally. $0.1 \mu \mathrm{~F}$ should be placed on the logic supply pin, and $10 \mu \mathrm{~F}$ placed between the common VLED line and the device ground at least at every second device.

## Package Power Dissipation ( $\mathbf{P}_{\mathrm{D}}$ )

The maximum allowable package power dissipation based on package type is determined by:

$$
\mathrm{P}_{\mathrm{D}(\max )}=\left(150-\mathrm{T}_{\mathrm{A}}\right) / \mathrm{R}_{\theta \mathrm{JA}},
$$

where $R_{\theta J A}$ is the thermal resistance of the package mounted on the circuit board, determined experimentally. Power dissipation levels based on the package are shown in the Package Thermal Characteristics section (see page 7).
The actual package power dissipation is determined by:

$$
\mathrm{P}_{\mathrm{D}(\text { act })}=\mathrm{DC} \times\left(\mathrm{V}_{\mathrm{DS}} \times \mathrm{I}_{\mathrm{O}} \times 16\right)+\left(\mathrm{V}_{\mathrm{DD}} \times \mathrm{I}_{\mathrm{DD}}\right)
$$

where DC is the duty cycle. The value 16 represents the maximum number of available device outputs.
When the load supply voltage, $\mathrm{V}_{\mathrm{LED}}$, is greater than 3 to 5 V , and $\mathrm{P}_{\mathrm{D}(\text { act })}>\mathrm{P}_{\mathrm{D}(\max )}$, an external voltage reducer ( $\mathrm{V}_{\mathrm{DROP}}$ ) must be used (see figure 12).
Reducing the percent duty cycle, DC, will also reduce power dissipation.

## 16-Channel Constant-Current Latched LED Driver with Open LED Detection and Dot Correction

Package ET, $5 \mathrm{~mm} \times 5 \mathrm{~mm}$, 32-pin QFN with Exposed Thermal Pad
