## **AS3643**

# 1300mA High Current LED Flash Driver

# 1 General Description

The AS3643 is an inductive high efficient DCDC step up converter with two current sinks. The DCDC step up converter operates at a fixed frequency of 4MHz and includes soft startup to allow easy integration into noise sensitive RF systems. The two current sinks can operate in flash / torch / assist (=video) light modes.

The AS3643 includes flash timeout, overvoltage, overtemperature, undervoltage and LED short circuit protection functions. A TXMASK/TORCH function reduces the flash current in case of parallel operation to the RF power amplifier and avoids a system shutdown. Alternatively this pin can be used to directly operate the torch light directly.

The AS3643 is controlled by an I<sup>2</sup>C interface and has a hardware automatic shutdown if SCL=0 for 100ms. Therefore no additional enable input is required for shutting down of the device once the system shuts down.

The AS3643 is available in a space-saving WL-CSP package measuring only 2.25x1.5x0.6mm and operates over the -30°C to +85°C temperature range.

Figure 1. Typical Operating Circuit

# 2 Key Features

- High efficiency 4MHz fixed frequency DCDC Boost converter with soft start allows small coils
  - Stable even in coil current limit
- LED current adjustable up to 1300mA
- Automatic current adjustment for low battery voltage
- PWM operation for lower output current for reliable light output of the LED; running at 31.25kHz to avoid audible noise
- Protection functions:
   Automatic Flash Timeout timer to protect the LED(s)
   Overvoltage and undervoltage Protection
   Overtemperature Protection
   LED short/open circuit protection
- I<sup>2</sup>C Interface with automatic shutdown
- 5V constant voltage mode operation
- Available in tiny WL-CSP Package, 13 balls 0.5mm pitch 2.25x1.5x0.6mm, package size

# 3 Applications

Flash/torch/videolight for smartphones, feature-phones, tablets, DSCs, DVCs

# 4 Pinout

## **Pin Assignment**

Figure 2. Pin Assignments (Top View)

# **Pin Description**

Table 1. Pin Description for AS3643

| Pin Number | Pin Name | Description  |  |  |  |  |  |
|------------|----------|--|--|--|--|--|--|
| A1         | VOUT1    | DCDC converter output capacitor - make a short connection to CVOUT / VOUT2   |  |  |  |  |  |
| A2         | GND      | Power and analog ground; make a short connection between both balls  |  |  |  |  |  |
| A3         | LED_OUT1 | Flash LED current sink   |  |  |  |  |  |
| B1         | SW1      | DCDC converter switching node - make a short connection to SW2 / coil LDCDC  |  |  |  |  |  |
| B2         | GND      | Power and analog ground; make a short connection between both balls  |  |  |  |  |  |
| C1         | VOUT2    | DCDC converter output capacitor - make a short connection to CVOUT / VOUT1   |  |  |  |  |  |
| C2         | SW2      | DCDC converter switching node - make a short connection to SW1 /coil LDCDC   |  |  |  |  |  |
| C3         | LED_OUT2 | Flash LED current sink   |  |  |  |  |  |
| D1         | SCL      | serial clock input for I <sup>2</sup> C interface  |  |  |  |  |  |
| D2         | VIN      | Positive supply voltage input - connect to supply and make a short connection to input capacitor CVIN and to coil LDCDC  |  |  |  |  |  |
| E1         | SDA      | serial data input/output for I <sup>2</sup> C interface (needs external pullup resistor)   |  |  |  |  |  |
| E2         | STROBE   | Digital input with pulldown to control strobe time for flash function  |  |  |  |  |  |
|            | TXMASK/  | Function 1: Connect to RF power amplifier enable signal - reduces currents during flash to avoid a system shutdown due to parallel operation of the RF PA and the flash driver |  |  |  |  |  |
| E3         | TORCH    | Function 2: Operate torch current level without using the I <sup>2</sup> C interface to  |  |  |  |  |  |
|            |          | operate the torch without need to start a camera processor (if the I <sup>2</sup> C is connected to the camera processor   |  |  |  |  |  |

# 5 Absolute Maximum Ratings

Stresses beyond those listed in Table 3 may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in Table 4, "Electrical Characteristics," on page 4 is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 3. Absolute Maximum Ratings

| Parameter   | Min  | Max             | Units | Comments  |  |
|---|------|-----------------|-------|---|--|
| VIN to GND  | -0.3 | +7.0            | V     |   |  |
| STROBE, TXMASK/TORCH, SCL, SDA to GND                 | -0.3 | VIN +<br>0.3    | V     | max. +7V  |  |
| SW1/2, VOUT1/2, LED_OUT1/2 to GND                     | -0.3 | +7.0            | V     | 110   |  |
| VOUT1/2 to SW1/2                                      | -0.3 |                 | V     | Note: Diode between VOUT1/2 and SW1/2   |  |
| voltage between GND pins                              | 0.0  | 0.0             | V     | short connection recommended  |  |
| Input Pin Current without causing latchup             | -100 | +100<br>+lin    | mA    | Norm: EIA/JESD78  |  |
| Continuous Power Dissipation (T <sub>A</sub> = +70°C) |      |                 |       |   |  |
| Continuous power dissipation                          |      | 1230            | mW    | Рт at 70°С <sup>1</sup>   |  |
| Continuous power dissipation derating factor          |      | 16.7            | mW/°C | PDERATE <sup>2</sup>  |  |
| Electrostatic Discharge                               |      |                 |       |   |  |
| ESD HBM   | 6    | ±8000           | V     |   |  |
| pins LED_OUT1/2 <sup>3</sup>                          |      |                 |       | Norm: JEDEC JESD22-A114F  |  |
| ESD HBM   |      | ±2000           | V     |   |  |
| ESD CDM   |      | ±500            | V     | Norm: JEDEC JESD 22-C101E   |  |
| ESD MM  |      | ±100            | V     | Norm: JEDEC JESD 22-A115-B  |  |
| Temperature Ranges and Storage Condition              | ns   |                 |       |   |  |
| Junction to ambient thermal resistance                | 9    | 60 <sup>4</sup> | °C/W  | For more information about thermal metrics, see application note AN01 Thermal Characteristics |  |
| Junction Temperature                                  |      | +150            | °C    | Internally limited (overtemperature protection), max. 20000s                                  |  |
| Storage Temperature Range                             | -55  | +125            | °C    |   |  |
| Humidity  | 5    | 85              | %     | Non condensing  |  |
| Body Temperature during Soldering                     |      | +260            | °C    | according to IPC/JEDEC J-STD-020  |  |
| Moisture Sensitivity Level (MSL)                      | MS   | 6L 1            |       | Represents a max. floor life time of unlimited  |  |

- 1. Depending on actual PCB layout and PCB used measured on demoboard; for peak power dissipation during flashing see document 'AS3643 Thermal Measurements'
- 2. PDERATE derating factor changes the total continuous power dissipation (PT) if the ambient temperature is not 70°C. Therefore for e.g. TAMB=85°C calculate PT at 85°C = PT PDERATE \* (85°C 70°C)
- 3. Pins LED\_OUT1 connected to LED\_OUT2 and capacitor Cvout connected to VOUT1/2 and GND; both GND pins connected together
- 4. Measured on AS3643 Demoboard.

# **6 Electrical Characteristics**

VVIN = +2.7V to +4.4V, TAMB =  $-30^{\circ}$ C to  $+85^{\circ}$ C, unless otherwise specified. Typical values are at VVIN = +3.7V, TAMB =  $+25^{\circ}$ C, unless otherwise specified.

Table 4. Electrical Characteristics

- 1. For VBAT=4.5V, SCL=1.8V, SDA=1.8V maximum ISTANBY is <16µA.
- 2. To improve efficiency at low output currents, the active part of the internal switching transistor PMOS is reduced in size to 1/5 its original size. This reduces the current required to drive the PMOS transistor and therefore improves overall efficiency at low output currents.
- 3. Due to slope compensation of the current limit, ILIMIT changes with duty cycle.
- 4. The logic input levels VIH and VIL allow for 1.2V or 1.8V supplied driving circuit
- 5. A pulldown current of  $36\mu A$  is equal to a pulldown resistor of  $42k\Omega$  at 1.5V
- 6. After this period, the first clock pulse is generated.
- 7. A device must internally provide a hold time of at least 300ns for the SDA signal (referred to the V<sub>IHMIN</sub> of the SCL signal) to bridge the undefined region of the falling edge of SCL.
- 8. A fast-mode device can be used in a standard-mode system, but the requirement  $t_{SU:DAT}$  = to 250ns must then be met. This is automatically the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line  $t_R$  max +  $t_{SU:DAT}$  = 1000 + 250 = 1250ns before the SCL line is released.

# 8 Detailed Description

The AS3643 is a high performance DCDC step up converter with internal PMOS and NMOS switches. Its output is connected to one flash LED with an internal current sink. The device is controlled by the pins SDA and SCL in I<sup>2</sup>C mode.

The actual operating mode like standby, assist light, indicator or flash mode, can then be chosen by the interface. If not in standby mode, the device automatically enters shutdown mode by keeping SCL low for more than tTIMEOUT<sup>1</sup>.

The AS3643 includes a fixed frequency DCDC step-up with accurate startup control. Together with the current sink (on LED OUT1/2) it includes several protection and safety functions.

## **Internal Circuit Diagram**

Figure 16. Internal circuit Diagram

## Softstart / Soft ramp down

During startup and ramp down the LED current is smoothly ramped up and ramped down. If the DCDC converter goes out of regulation (measured by monitoring the voltage across the current sinks), the ramp up is temporarily stopped in order for the DCDC to return to regulation<sup>2</sup>.

<sup>1.</sup> Following registers are reset to their default value if the timeout expires: out\_on=0, ext\_torch\_on=00, mode setting=00, const v mode=0.

<sup>2.</sup> The actual value of the LED current setting can be readout by the register led\_current\_actual (see page 26) to allow the camera processor to adopt to the actual operating conditions.

## 4MHz/1MHz Operating Mode Switching

If freq\_switch\_on (see page 26)=1 and in flash and assist light mode (indicator mode or low current mode using PWM mode -see mode\_setting (page 24) - always will use pulseskip) if led\_current>=40h, the DCDC converter always operates in PWM mode (exception: PFM mode is allowed during startup) to reduce EMI in EMI sensitive systems. For flash and assist light mode and high duty cycles close to 100% on-time (maximum duty cycle) of the PMOS, the DCDC con-

verter can switch into a 1MHz operating mode and maximum duty cycle to improve efficiency for this load condition<sup>3</sup>. The DCDC converter returns back to its normal 4MHz operating frequency when load or supply conditions change. Due to this switching between two fixed frequencies the noise spectrum of the system is exactly defined and predictable. If improved efficiency is required, the fixed switching between 1MHz / 4MHz can be disabled by freq\_switch\_on (see page 26)=0. In this case pulseskip will be used.

The internal circuit for switching between these two frequencies is shown in Figure 17:

**V**BAT SW1/2 AS3643 force DCDC PWM **V**VOUTMAX div 4 Open LED iclk detect (fault\_ovp) 0 clk low\_vds LED OUT1 or LED OUT2 4MHz reset Set/Res FF 50µs deb. set freq\_switch\_on high\_vds VHIGH\_VDS

Figure 17. Internal circuit of 4MHz/1Mhz selection

Note: For simplicity Figure 17 shows only a single current sink.

## **Protection and Fault Detection Functions**

The protection functions protect the AS3643 and the LED(s) against physical damage. In most cases a Fault register bit is set, which can be readout by the  $I^2C$  interface. The fault bits are automatically cleared by a  $I^2C$  readout of the fault register. Additionally the DCDC is stopped and the current sinks are disabled by resetting out\_on=0, mode setting=00 and ext\_torch\_on=00.

## **Overvoltage Protection**

In case of no or a broken LED(s) at the pin LED\_OUT1/2 and an enabled DCDC converter, the voltage on VOUT1/2 rises until it reaches Vvoutmax (overvoltage condition) and the voltage across the current source is below low\_vds<sup>5</sup>., the DCDC converter is stopped, the current sources are disabled and the bit fault\_ovp (see page 25) is set<sup>6</sup>.

<sup>3.</sup> Efficiency compared to a 4MHz only DCDC converter forced to operate with minimum duty cycle.

<sup>4.</sup> Applies for all faults except TXMASK event occurred

<sup>5.</sup> If overvoltage is reached, but none of the low\_vds comparator(s) triggers, VOUT1/2 is still regulated below VVOUTMAX.

<sup>6.</sup> In constant voltage mode (5V generation, register bit const\_v\_mode=1) this fault is disabled.

#### **Short Circuit Protection**

After the startup of the DCDC converter, the voltage on LED\_OUT1/2 is continuously monitored and compared against VLEDSHORT if the LED current is above 20mA<sup>7</sup> (see Figure 18). If the voltage across the LED (VFLED = VOUT1/2-LED\_OUT1/2) stays below VLEDSHORT, the DCDC is stopped (as a shorted LED is assumed), the current sinks are disabled and the bit fault led short (see page 25) is set.

Figure 18. Short LED detection

#### **Overtemperature Protection**

The junction temperature of the AS3643 is continuously monitored. If the temperature exceeds TOVTEMP, the DCDC is stopped, the current sinks are disabled (instantaneous) and the bit fault\_overtemp (see page 25) is set. The driver is automatically re-enabled once the junction temperature drops below TOVTEMP-TOVTEMPHYST.

#### **TXMASK** event occurred

If during flash, TXMASK current reduction is enabled (see TXMASK on page 15, configured by ext\_torch\_on=01) and a TXMASK event happened (pin TXMASK/TORCH=1), the fault register bit fault txmask (see page 25) is set.

## **Flash Timeout**

If the flash is started a timeout timer is started in parallel. If the flash duration defined by the STROBE input (strobe\_on = 1 and strobe\_type = 1, see Figure 25 on page 17) exceeds tflashtimeout (adjustable by register flash\_timeout (see page 24)), the DCDC is stopped and the flash current sinks (on pin LED\_OUT1/2) are disabled and fault\_timeout is set

If the flash duration is defined by the timeout timer itself (strobe\_on = 0, see Figure 23 on page 17), the register fault timeout is set after the flash has been finished.

#### **Supply undervoltage Protection**

If the voltage on the pin VIN (=battery voltage) is or falls below VuvLo, the AS3643 is kept in shutdown state and all registers are set to their default state.

#### Wakeup Circuit - Power off detection

In flash, assist light and indicator mode (register mode\_setting (page 24)=01, 10 or 11) and out\_on (page 24)=1, if SCL is L for more than tTIMEOUT, shutdown mode is automatically entered. This feature automatically detects a power-off of the controlling circuit driving SCL and SDA (VDD\_I/F goes to 0V e.g. due to a low power condition of the driving circuit) - the internal circuit is shown in Figure 19:

<sup>7.</sup> To avoid errors in short LED detection for LEDs with a high leakage current

<sup>8.</sup> In constant voltage mode (const v mode=1) the DCDC will not be automatically re-enabled.

Figure 19. Device Shutdown and Wakeup

In shutdown mode once pin SCL goes high for the first time, the internal counter shown in Figure 19 is immediately reset thus releasing the internal RESET (assuming VIN is above VuvLo) signal and allows instant communication on the I<sup>2</sup>C bus. Therefore no additional action is required to leave the shutdown mode and start I<sup>2</sup>C communication.

#### Purpose of this circuit

The purpose of this circuit is an additional security mechanism.

Assume the user programmed torch or indicator operation (there is no timeout for these operating modes) and the battery slowly drops below the undervoltage limit of the system. The processor would get an reset by the PMIC and the LDO operating VDD\_I/F is switched off, but the processor might not have been able to switch-off the torch/indicator operation of the AS3643. Due to the implemented security mechanism the AS3643 detects a power off of VDD\_I/F and automatically enters shutdown.

## Current consumption in standby/shutdown mode

The AS3643 is designed to draw minimum current in standby and shutdown mode. There is a small difference in current consumption between these two operating modes (typ. 300nA) only due to the internal level shifters (see the schmitt trigger input buffers connected to SCL and SDA in Figure 19) for shifting up the voltage on SCL/SDA (VDD\_I/F e.g. 1.8V) to the supply voltage on VIN (e.g. 3.7V). If the AS3643 is driven with digital levels close to 0V/VIN, the current consumption for standby mode is identical to shutdown mode.

## **Operating Mode and Currents**

The output currents and operating mode are selected according to the following table:

Table 5. Operating Mode and current settings

- 1. SCL low for tTIMEOUT and operating mode is indicator, assist or flash mode then shutdown mode is entered.
- 2. The MSB bit of this register not used to protect the LED; therefore the maximum assist / torch light current = half the maximum flash current
- 3. The low current mode is a general purpose PWM mode to drive less current through the LED in average, but keep the actual pulsed current in a range where the light output from the LED is still specified. As only the 6 LSBs of led\_current are used the maximum current is limited to 1/4 of the maximum flash current.

#### **Flash Current Reductions**

#### **TXMASK**

Usually the flash current is defined by the register led\_current . If the TXMASK/TORCH input is used and (configured by ext\_torch\_on=01), the flash current is reduced to flash txmask\_current if TXMASK/TORCH=1.

#### Current Reduction by VIN measurements in Flash Mode

Due to the high load of the flash driver and the ESR of the battery (especially critical at low temperatures), the voltage on the battery drops. If the voltage drops below the reset threshold of the system would reset. To prevent this condition the AS3643 monitors the battery voltage and keeps it above vin low v run as follows:

Before a flash is started the voltage on VIN is measured. If the voltage is below the setting of vin\_low\_v the fault\_uvlo (see page 25) is set and the flash is disabled (driver stays in shutdown) if vin\_low\_v\_shutdown=1. The flash current is reduced to flash txmask current if vin low v shutdown=0.

During flash, if the voltage on VIN drops below the threshold defined by vin\_low\_v\_run, the flash current is reduced (or ramping of the current is stopped during flash current startup) and fault\_uvlo is set. The timing for the reduction of the current is 8µs/LSB current change.

During the flash pulse the actual used current can be readout by the register led current actual.

After the flash pulse the minimum current can be readout by the register led\_current\_min - this allows to adjust the camera sensitivity (gain or iso-settings) for the subsequent flash pulse (e.g. when using a pre-flash and a main flash pulse).

The internal circuit for low voltage current reductions are shown in Figure 20:

Figure 20. Low Voltage current Reduction Internal Circuit

A mobile phone camera flash system can trigger a diagnostic flash and a main-flash:

The diagnostic flash is initiated by the processor. After this diagnostic flash, the determined maximum flash current can be read back through the I<sup>2</sup>C interface from register led\_current\_min (see page 26) and used for the setting for the main flash. Therefore the current in the main-flash is constant and additionally the camera system can use this current for picture quality adjustments - the waveforms for this concept are shown in Figure 21:

Voltage reduction due Voltage reduction due to ESR and Flash to additional load **Driver Load** (e.g. camera sensor) **VBAT VBAT I**FLASH vin low v run use same **I**FLASH current diagnostic Main Flash Flash Shoot Image Processor report min. IFLASH adjusts gain with constant and well to Processor defined flash current of Image Sensor (led current min)

Figure 21. Low Voltage current Reduction Waveform with diagnostic-Flash and Main-Flash Phase

If the diagnostic flash should be short (e.g. 10ms) it is recommended to operate this diagnostic flash at slightly higher vin\_low\_v\_run setting compared to the main flash as shown in Figure 22:

Voltage reduction due use higher vin low v run for diagnostic flash to ESR and Flash than for actual main flash **Driver Load VBAT VBAT I**FLASH zzvin low v run use same **I**FLASH current diagnostic-Main Flash Flash report min. IFLASH Process... adjusts gain Shoot Image with constant and well (led\_current\_min) of Image Sensor defined flash current

Figure 22. Low Voltage current Reduction Waveform with short diagnostic-Flash and Main-Flash Phase

The different settings for vin\_low\_v\_run allow a constant main flash current without dropping VIN below vin\_low\_v\_run.

## Flash Strobe Timings

The flash timing are defined as follows:

- Flash duration defined by register flash\_timeout and flash is started immediately when this mode is selected by the I<sup>2</sup>C command (see Figure 23): set strobe on = 0, start the flash by setting out on = 1
- Flash duration defined by register flash\_timeout and flash started with a rising edge on pin STROBE (see Figure 24):
   set strobe\_on = 1 and strobe\_type = 0
- Flash start and timing defined by the pin STROBE; the flash duration is limited by the timeout timer defined by flash\_timeout (see Figure 25 and Figure 26): set strobe\_on = 1 and strobe\_type = 1

Figure 23. AS3643 flash duration defined by flash\_timeout without using STROBE input

Figure 24. AS3643 flash duration defined by flash\_timeout, starting flash with STROBE rising edge

Figure 25. AS3643 flash duration and start defined by STROBE, limited by flash\_timeout; timer not expired

Figure 26. AS3643 flash duration and start defined by STROBE, limited by flash\_timeout; timer expired

## I<sup>2</sup>C Serial Data Bus

The AS3643 supports the I<sup>2</sup>C bus protocol. A device that sends data onto the bus is defined as a transmitter and a device receiving data as a receiver. The device that controls the message is called a master. The devices that are controlled by the master are referred to as slaves. A master device that generates the serial clock (SCL), controls the bus access, and generates the START and STOP conditions must control the bus. The AS3643 operates as a slave on the I<sup>2</sup>C bus. Within the bus specifications a standard mode (100kHz maximum clock rate) and a fast mode (400kHz maximum clock rate) are defined. The AS3643 works in both modes. Connections to the bus are made through the open-drain I/O lines SDA and SCL.

The following bus protocol has been defined (Figure 27):

- Data transfer may be initiated only when the bus is not busy.
- During data transfer, the data line must remain stable whenever the clock line is HIGH. Changes in the data line while the clock line is HIGH are interpreted as control signals.

Accordingly, the following bus conditions have been defined:

#### **Bus Not Busy**

Both data and clock lines remain HIGH.

#### Start Data Transfer

A change in the state of the data line, from HIGH to LOW, while the clock is HIGH, defines a START condition.

#### Stop Data Transfer

A change in the state of the data line, from LOW to HIGH, while the clock line is HIGH, defines the STOP condition.

#### Data Valid

The state of the data line represents valid data when, after a START condition, the data line is stable for the duration of the HIGH period of the clock signal. The data on the line must be changed during the LOW period of the clock signal. There is one clock pulse per bit of data.

Each data transfer is initiated with a START condition and terminated with a STOP condition. The number of data bytes transferred between START and STOP conditions are not limited, and are determined by the master device. The information is transferred byte-wise and each receiver acknowledges with a ninth bit.

#### Acknowledge

Each receiving device, when addressed, is obliged to generate an acknowledge after the reception of each byte. The master device must generate an extra clock pulse that is associated with this acknowledge bit.

A device that acknowledges must pull down the SDA line during the acknowledge clock pulse in such a way that the SDA line is stable LOW during the HIGH period of the acknowledge-related clock pulse. Of course, setup and hold times must be taken into account. A master must signal an end of data to the slave by not generating an acknowledge bit on the last byte that has been clocked out of the slave. In this case, the slave must leave the data line HIGH to enable the master to generate the STOP condition.

Figure 27. Data Transfer on I<sup>2</sup>C Serial Bus

Depending upon the state of the R/W bit, two types of data transfer are possible:

- 1. **Data transfer from a master transmitter to a slave receiver.** The first byte transmitted by the master is the slave address. Next follows a number of data bytes. The slave returns an acknowledge bit after each received byte. Data is transferred with the most significant bit (MSB) first.
- 2. Data transfer from a slave transmitter to a master receiver. The master transmits the first byte (the slave address). The slave then returns an acknowledge bit, followed by the slave transmitting a number of data bytes. The master returns an acknowledge bit after all received bytes other than the last byte. At the end of the last received byte, a "not acknowledge" is returned. The master device generates all of the serial clock pulses and the START and STOP conditions. A transfer is ended with a STOP condition or with a repeated START condition. Since a repeated START condition is also the beginning of the next serial transfer, the bus is not released. Data is transferred with the most significant bit (MSB) first.

The AS3643 can operate in the following two modes:

- 1. Slave Receiver Mode (Write Mode): Serial data and clock are received through SDA and SCL. After each byte is received an acknowledge bit is transmitted. START and STOP conditions are recognized as the beginning and end of a serial transfer. Address recognition is performed by hardware after reception of the slave address and direction bit (see Figure 28). The slave address byte is the first byte received after the master generates the START condition. The slave address byte contains the 7-bit AS3643 address, which is 0110000, followed by the direction bit (R/W), which, for a write, is 0. After receiving and decoding the slave address byte the device outputs an acknowledge on the SDA line. After the AS3643 acknowledges the slave address + write bit, the master transmits a register address to the AS3643. This sets the register pointer on the AS3643. The master may then transmit zero or more bytes of data, with the AS3643 acknowledging each byte received. The address pointer will increment after each data byte is transferred. The master generates a STOP condition to terminate the data write.
- 2. Slave Transmitter Mode (Read Mode): The first byte is received and handled as in the slave receiver mode. However, in this mode, the direction bit indicates that the transfer direction is reversed. Serial data is transmitted on SDA by the AS3643 while the serial clock is input on SCL. START and STOP conditions are recognized as the beginning and end of a serial transfer (Figure 29 and Figure 30). The slave address byte is the first byte received after the master generates a START condition. The slave address byte contains the 7-bit AS3643 address, which is 0110000, followed by the direction bit (R/W), which, for a read, is 1. After receiving and decoding the slave address byte the device outputs an acknowledge on the SDA line. The AS3643 then begins to transmit data starting with the register address pointed to by the register pointer. If the register

<sup>9.</sup> The address for writing to the AS3643 is 60h = 01100000b

<sup>10.</sup> The address for read mode from the AS3643 is 61h = 01100001b

pointer is not written to before the initiation of a read mode the first address that is read is the last one stored in the register pointer. The AS3643 must receive a "not acknowledge" to end a read.

| 6   | fault_led_short | 0   | R/sC <sup>1</sup> | 0   | No fault  |  |  |  |
|     |                 |   |                   | 1   | A shorted LED is detected (pin LED_OUT1/2)      |  |  |  |
|     |                 |   |                   |   | see Overvoltage Protection on page 11           |  |  |  |
| 7   | fault_ovp       | 0   | R/sC <sup>1</sup> | 0   | No fault  |  |  |  |
|     |                 |   |                   | 1   | An overvoltage condition is detected (pin VOUT) |  |  |  |

1. R/sC = Read, self clear; after readout the register is automatically cleared

Table 15. PWM and Indicator Register

|         |                 | PWM and Indicator Register  |                    |   |  |  |  |  |
|---------|-----------------|---|--------------------|---|--|--|--|--|
| Addr: 9 |                 | This register defines the PWM mode (e.g. for indicator) and 4/1MHz mode switching |                    |   |  |  |  |  |
| Bit     | Bit Name        | Default   | Access             | Description   |  |  |  |  |
|         |                 |   |                    | Define the AS3643 PWM with 31.25kHz operation for indicator or low current mode (mode_setting=01)   |  |  |  |  |
|         | 1:0 inct_pwm 00 |   | 00 1/16 duty cycle |   |  |  |  |  |
| 1:0     |                 | 00  | R/W                | 01 2/16 duty cycle  |  |  |  |  |
|         |                 |   |                    | 10 3/16 duty cycle  |  |  |  |  |
|         |                 |   |                    | 11 4/16 duty cycle  |  |  |  |  |
|         |                 |   |                    | Exact frequency switching between 4MHz/1MHz for ass<br>and flash modes for operation close to maximum<br>pulsewidth   |  |  |  |  |
| 2       | freq_switch_on  | 0   | R/W                | Pulseskip operation is allowed for all modes - results in better efficiency   |  |  |  |  |
|         |                 |   |                    | In flash and assist light mode (indicator mode or locurrent mode using PWM always will use pulseskip led_current>=40h, the DCDC is running at 4MHz 1MHz (pulseskip is disabled) - results in improve noise performance; |  |  |  |  |

Table 17. Minimum LED Current Register

|     |                               | Minimum LED Current Register  |        |  |  |  |
|-----|-------------------------------|---|--------|--|--|--|
|     | Addr: Eh                      | This register reports the minimum LED current from the last operation cycle |        |  |  |  |
| Bit | Bit Name                      | Default   | Access | Description  |  |  |
| 7:0 | led_current_min <sup>12</sup> | 00h   | R      | Minimum current through the current sink (only including all current reductions as described in Current Reduction by VIN measurements in Flash Mode excluding current reductions caused by TXMASK) |  |  |

- 1. As the internal change of this register is asynchronous to the readout, it is recommended to readout the register after the flash pulse. The register will store the minimum current through the LED after e.g. a previous flash. This current can be used for a subsequent flash pulse for a safe operating range.
- 2. This register is only set if an actual current reduction happens (fault\_uvlo (see page 25)=1) otherwise led\_current\_min=0.

Table 18. Actual LED Current Register

|     | Addr: Fh                        | Actual LED Current Register                      |        |  |  |  |
|-----|---------------------------------|--|--------|--|--|--|
|     | Addi. Fii                       | This register reports the actual set LED current |        |  |  |  |
| Bit | Bit Name                        | Default  | Access | Description  |  |  |
| 7:0 | led_current_actual <sup>1</sup> | 00h  | R      | Actual set current through the current sink (including all current reductions as described in Flash Current Reductions including LED current ramp up/down) |  |  |

<sup>1.</sup> As the internal change of this register is asynchronous to the readout, it is recommended to readout the register twice and compare the results.

<sup>1.</sup> Always write'0' to undefined register bits (e.g. to bits 4..7 of register 6)

# 9 Application Information

## **External Components**

## Input Capacitor CVIN

Low ESR input capacitors reduce input switching noise and reduce the peak current drawn from the battery. Ceramic capacitors are required for input decoupling and should be located as close to the device as is practical.

Table 22. Recommended Input Capacitor

| Part Number       | С                              | TC Code | Rated<br>Voltage | Size | Manufacturer                   |
|-------------------|--------------------------------|---------|------------------|------|--------------------------------|
| GRM188R60J106ME47 | 10μ<br>>3μF@4.5V<br>>2μF@5.25V | X5R     | 6V3              | 0603 | Murata<br>www.murata.com       |
| LMK107BBJ106MA    | 10μ<br>>3μF@4.5V               | X5R     | 6V3              | 0603 | Taiyo Yuden<br>www.t-yuden.com |

If a different input capacitor is chosen, ensure similar ESR value and at least 3µF capacitance at the maximum input supply voltage. Larger capacitor values (C) may be used without limitations.

Add a smaller capacitor in parallel to the input pin VIN (e.g. Murata GRM155R61C104, >50nF @ 3V, 0402 size).

## **Output Capacitor CVOUT**

Low ESR capacitors should be used to minimize VOUT ripple. Multi-layer ceramic capacitors are recommended since they have extremely low ESR and are available in small footprints. The capacitor should be located as close to the device as is practical.

X5R dielectric material is recommended due to their ability to maintain capacitance over wide voltage and temperature range.

Table 23. Recommended Output Capacitor

| Part Number                    | С                        | TC Code | Rated<br>Voltage | Size  | Manufacturer             |
|--------------------------------|--------------------------|---------|------------------|---|--------------------------|
| GRM219R61A116U                 | 10μF +/-10%<br>>4.2μF@5V | X5R     | 10V              | 0805  |                          |
| GRM188R60J106ME84 <sup>1</sup> | 10μF +/-20%<br>>4.2μF@4V | X5R     | 6.3V             | 0603<br>(1.6x0.8x0.85mm<br>max. 0.95mm<br>height) | Murata<br>www.murata.com |

<sup>1.</sup> Use only for VLED < 3.75V

If a different output capacitor is chosen, ensure similar ESR values and at least 4.2μF capacitance at 5V output voltage.

#### Inductor LDCDC

The fast switching frequency (4MHz) of the AS3643 allows for the use of small SMDs for the external inductor. The saturation current Isaturation should be chosen to be above the maximum value of ILIMIT<sup>11</sup>. The inductor should have very low DC resistance (DCR) to reduce the I<sup>2</sup>R power losses - high DCR values will reduce efficiency.

Table 24. Recommended Inductor

| Part Number   | L                                       | DCR            | <b>I</b> SATURATION             | Size                                      | Manufacturer  |

| MAKK2016T1R0M | 1.0µH<br>>0.6µH @ 2.75A                 | 65mΩ           | 2.0A <sup>3</sup>               | 2.0x1.6x1.0<br>mm<br>height is max        |   |

- 1. Do not exceed maximum Isaturation can be ensured by setting coil peak (will limit LED current)
- 2. Flash cycle limit: 150ms on, 500ms off; repeat maximum 50 times.(if used with default coil\_peak=0b (2A))
- 3. Set current limit to 2A ()coil\_peak=10b) can limit maximum output current.

If a different inductor is chosen, ensure similar DCR values and at least0.6µH inductance at ILIMIT.

## **PCB Layout Guideline**

The high speed operation requires proper layout for optimum performance. Route the power traces first and try to minimize the area and wire length of the two high frequency/high current loops:

Loop1: CVIN/CVIN2 - LDCDC - pin SW1/2 - pin GND - CVIN/CVIN2

Loop2: CVIN/CVIN2 - LDCDC - pin SW1/2 - pin VOUT1/2 - CVOUT - pin GND - CVIN/CVIN2

.

<sup>11.</sup>Can be adjusted in I<sup>2</sup>C mode with register coil\_peak (see page 22)

At the pin GND a single via (or more vias, which are closely combined) connects to the common ground plane. This via(s) will isolate the DCDC high frequency currents from the common ground (as most high frequency current will flow between Loop1 and Loop2 and will not pass the ground plane) - see the 'island' in Figure 31.

Figure 31. Layout recommendation

**Note:** If component placement rules allow, move all components close to the AS3643 to reduce the area and length of Loop1 and Loop2.

An additional 100nF (e.g. Murata GRM155R61C104, >50nF @ 3V, 0402 size) capacitor CVIN2 in parallel to CVIN is recommended to filter high frequency noise for the power supply of AS3643. This capacitor should be as close as possible to the GND/VIN pins of AS3643.

## **5V Operating Mode**

The AS3643 can be used to power a 5V system (e.g. audio amplifier). The operating mode is selected by setting register bit const\_v\_mode (page 23)=1. In this operating mode, the current sinks are disabled and cannot be switched on (no flash/torch operation is possible).

**Note:** There is always a diode between VIN and VOUT1/2 due to the internal circuit. Therefore VOUT1/2 cannot be completely switched off
